Overview

- Towards Machine Learning
 - Decision tree
 - Boosting decision tree
 - Keras-DNN
- 2 Apply Machine Learning to Measure Higgs CP via tth
 - Determine input variables
 - Response value and ROC curve
- 3 HZZ Channel

Machine Learning

Figure: Artificial intelligence

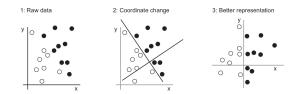

Figure: Coordinate change. Learning, in the context of machine learning, describes an automatic search process for better representations.

Common Models of Machine Learning

- Support vector machines
- Bayesian networks
- Boosting decision trees: AdaBoost, Gradient Boosting, XGBoost
- Artificial neural network

Decision tree

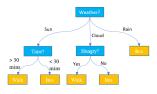

Figure: A decision tree

A decision tree takes a set of input features and splits input data recursively based on those features.

- Nodes
 - The data is split based on a value of one of features at each node.
 - Sometime called interior nodes
- Leaves
 - Terminal nodes
 - Represent a class label or probability
 - If the outcome is a continuous variable it's considered a regression tree

Decision tree

Learning:

- Each split at a node is chosen to maximize information gain(rate)
- The splits are created recursively

Note:

- Information gain is the difference in entropy before and after the potential split
- The process is repeated until some stop condition is met. Ex: depth of tree, no more information gain, etc...

Information Gain

category information entropy:

$$Info(D) = -\sum_{i}^{m} p_{i}log_{2}(p_{i})$$

feature information entropy:

$$Info_A(D) = \sum_{j=1}^{\nu} \frac{|D_j|}{|D|} * Info(D_j)$$

information gain: $Gain(A) = Info(D) - Info_A(D)$

Ren-Qi Pan (ZJU)

Information Gain Rate

feature splitting information entropy:

$$SplitInfo_A(D) = -\sum_{j=1}^{v} \frac{|D_j|}{|D|} log_2 \frac{|D_j|}{|D|}$$

information gain rate:

$$GainRate(A) = \frac{Gain(A)}{SplitInfo_A(D)}$$

Ren-Qi Pan (ZJU)

Boosting decision tree

Usually, a single tree is not strong enough to be used in practice. What is actually used is the ensemble model, which sums the prediction of multiple trees together.

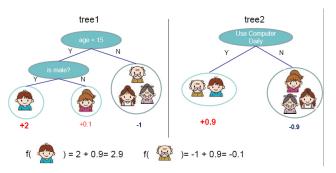

Figure: Here is an example of a tree ensemble of two trees. The prediction scores of each individual tree are summed up to get the final score

Tree boosting

Boosting is a method of combining many weak learners (trees) into a strong classifier.

- Each tree is created iteratively
- The trees output (h(x)) is given a weight (w) relative to its accuracy
- Use residual to create a new tree
- The ensemble output is the weighted sum: $\hat{y} = \sum_t w_t h_t(x)$
- After each iteration each data sample is given a weight based on its misclassification
 - Note: The more often a data sample is misclassified, the more important it becomes
- The goal is to minimize an objective function

Ren-Qi Pan (ZJU) tth July 9, 2019 10 / 27

Types of boosting

There are many different ways of iteratively adding learners to minimize a loss function. Some of the most common:

- AdaBoost
 - Adaptive Boosting
 - One of the originals
 - residual=prediction- real value
- Gradient Boosting
 - Uses gradient descent to create new learners
 - The loss function is differentiable
 - residual: minus gradient of loss function
- XGBoost
 - eXtreme Gradient Boosting
 - Type of gradient boosting
 - Objective Function: Training Loss + Regularization
 - Taylor expansion of the loss function up to the second order
 - Shrinkage and Column Subsampling

Keras and TensorFlow

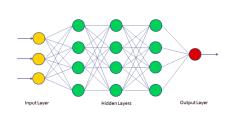

Keras:

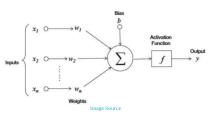

- model-level library(released in 27 March 2015)
- an open-source neural-network library written in Python
- providing high-level building blocks for developing deep-learning models

TensorFlow:

- TensorFlow is developed by Google(released in November 9, 2015)
- serving as the backend engine of Keras
- handle low-level operations such as tensor manipulation and differentiation

Mechanism of DNN

 $Y = \sum (weight * input) + bias$

- (a) mechanism of artificial neural network (b) Here's a diagram of what one node
 - might look like.

Ren-Qi Pan (ZJU) tth July 9, 2019 13 / 27

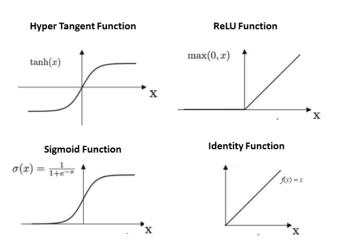

Figure: common activation function used in artificial neural network.

Components of neural network

Training a neural network revolves around the following objects:

- Layers, which are combined into a network (or model)
- The input data and corresponding targets
- The loss function, which defines the feedback signal used for learning
- The optimizer, which determines how to update weights

How neural network works?

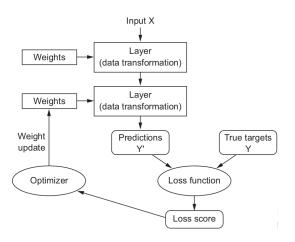

Figure: Relationship between the network, layers, loss function, and optimizer

An neural network model

```
model = models.Sequential()
model.add(layers.Dense(16, activation='relu', input_shape=(ndim,))
model.add(layers.Dense(16, activation='relu'))
model.add(layers.Dense(16, activation='relu'))
model.add(layers.Dense(1, activation='sigmoid'))
```

Figure: An example of artificial neural network model with 4 layers.

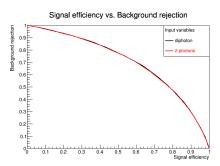

Signal efficiency vs. Background rejection
